FALL 2023

ABSTRACT

Breast Cancer remains as a significant global cause of Mortality among Women, emphasizing the crucial role of its Early Detection in reducing fatalities. Ultrasound Imaging is a valuable tool in Breast Cancer Diagnosis, but the accurate identification of lesions can be challenging. This project aims to Enhance the Detection of Breast Cancer Lesions in Ultrasound Images through Advanced Image Preprocessing Techniques. Thus, the project acts as a bridge to provide a solution using a MATLAB-based approach, that processes multiple PNG images in a loop, with each image undergoing a series of Preprocessing Steps. These steps include Noise Reduction, Edge Detection, Contrast Enhancement, and the Manual Selection of a Region of Interest (ROI) based on the User's Input. A simple Thresholding Technique is then applied within the ROI to Identify Potential Lesions, which are then displayed in color, enhancing their visibility.

The Sample Dataset used in the project is "Dataset_BUSI_with_GT,", comprising of breast ultrasound images that were amassed, focusing on women aged 25 to 75 Years in 2018. (*Breast Ultrasound Images Dataset*, n.d.) This dataset encompasses 780 PNG - Formatted Images, with an average size of 500 x 500 Pixels, originating from 600 female patients. The images are organized into 3 Distinct Categories: Normal, Benign, and Malignant, and further paired with their corresponding ground truth images. The integration of machine learning techniques with these breast ultrasound images offers promising prospects for Enhancing Breast Cancer Classification, Detection, and Segmentation (Al-Dhabyani et al., 2020).

Keywords: Breast Cancer, MATLAB, Image Preprocessing Techniques

INTRODUCTION

Breast Cancer, a formidable global health concern, poses a significant threat to the well-being of women worldwide. This disease remains one of the most common cancers globally, accounting for 1 in 8 cancer diagnoses and affecting millions of women annually. Incidence rates vary across regions, with higher occurrences in developed countries. As of January 2022, there was an estimation of more than 4 million women living with a history of breast cancer in the United States of America (Johnson, B., et al., 2023).

Breast cancer is idiopathic; however, the disease is attributed to several risk factors. These include genetic predisposition; hormonal influences; age, especially more risk for individuals over 40 years of age; lifestyle choices such as excess alcohol consumption; and environmental factors like exposure to radiations, obesity and overweight, menarche, menopause at an older age, no pregnancy or pregnancy at an older age, and hormone use of long-term contraceptives or postmenopausal Hormone Therapy.

The pathophysiology of breast cancer shows that the disease progresses rapidly when the abnormally dividing cells accumulate to form lumps and further metastasize, spreading to the lymph nodes or other parts of the body (*Mammography*, 2020). Most breast malignancies arise from epithelial elements and are categorized as carcinomas, a diverse group of lesions that differ in microscopic appearance and biologic behavior.

Regular screening, early detection, and advancements in diagnostic technologies are imperative components in the ongoing efforts to mitigate the impact of breast cancer on women's health worldwide. The most useful diagnostic tools for breast cancer are physical examination, Mammography, Ultrasound Imaging, Magnetic Resonance Imaging (MRI) and Biopsy (Aishaniko, 2023).

The increased prevalence of breast cancer has posed the need for timely detection and diagnosis, which proved to be pivotal for successful treatment outcomes. Early detection has several benefits including the improved chances of survival, easier and efficient treatment plans, and finally, reduction in healthcare expenses. In this regard, ultrasound imaging has emerged as a widely adopted method for breast cancer screening and diagnosis, offering simplicity, absence of ionizing radiation, and real-time imaging capabilities. However, challenges such as high noise, robust artifacts, and low tissue contrast in ultrasound images impede the efficacy of breast cancer screening.

To overcome these challenges, researchers are actively engaged in developing advanced image preprocessing techniques to enhance the quality of breast ultrasound images and improve the detection of cancerous lesions. Methods such as contrast enhancement through segmentation-based approaches, utilizing tools like Contrast Limited Adaptive Histogram Equalization (CLAHE) and Side Window Filters (SWF), prove effective in highlighting lesion contours while mitigating the impact of noise (Shaukat, F., et al., 2017).

The evolution of ultrasound-based Computer-Aided Diagnosis (CAD) systems is noteworthy, as these intelligent systems can automatically screen and diagnose breast cancer (Smith, A., et al., 2022). Tasks such as lesion detection, segmentation, and diagnosis are seamlessly performed when presented with real-time images, marking a significant advancement in the field.

On the other hand, in the realm of Deep Learning, advanced models show promising outcomes in the detection and classification of breast lesions (Suradi, S., H., et al., 2021). For example, the use of anchor-free networks has demonstrated a Mean Average Precision (mAP) of 0.902 in experiments, underscoring the potential of deep learning in enhancing diagnostic capabilities (Zebari, D., A., et al., 2020).

In conclusion, the ongoing research into advanced image preprocessing techniques for breast ultrasound holds promise for significantly improving early breast cancer detection and diagnosis. However, it is crucial to acknowledge that these techniques are still in the developmental stage, requiring further validation to ensure their effectiveness and reliability.

PURPOSE OF PROJECT

This Project aims to enhance the detection of Breast Cancer lesions in Ultrasound Images through Advanced Image Preprocessing Techniques and serves as a bridge to provide a solution using a MATLAB-based approach that processes multiple PNG images in a loop. Each image undergoes a series of Preprocessing Steps, including:

1. Noise Reduction:

This step aims to binarize and remove random variations of brightness or color in images that can distort the image quality and hinder the identification of lesions.

2. Edge Detection:

This process creates a binary mask and identifies the boundaries of objects within images, which can help in delineating potential lesions.

3. Contrast Enhancement:

This technique improves the visibility of subtle features in the lesions image by using the inversion of binary mask method, to increase the difference in light intensity.

4. Manual Selection of a Region of Interest (ROI):

Based on the user's input, a specific region of the image is selected for further analysis. This allows for focused examination of areas that are most likely to contain lesions.

After these steps, a simple Thresholding Technique is applied within the ROI to identify potential lesions, which are then displayed to the user, while safeguarding the patients' demographics. Thus, the project complies with the Health Insurance Portability and Accountability Act of 1996 (HIPAA) checklist for ensuring Medical Data Safety.

The insights gained from this project, along with the report of current trends, will provide data-driven insights into strategies for early detection, and developing effective interventions to reduce the burden of Breast Cancer.

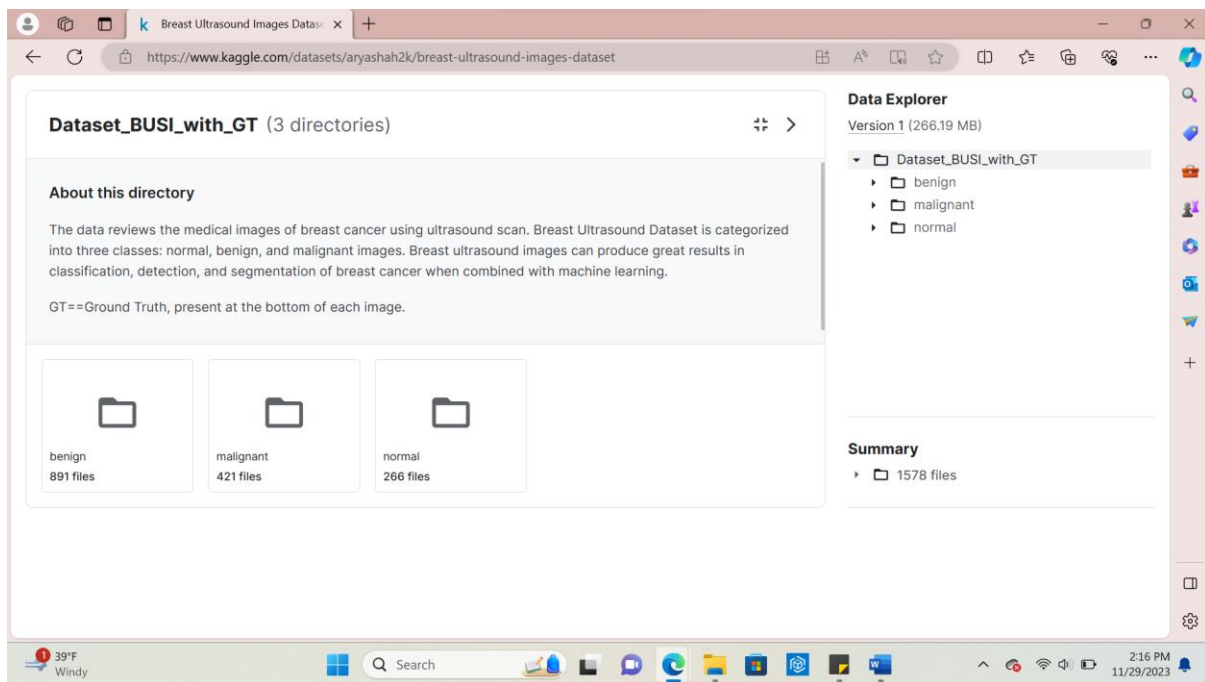

STUDY METHODOLOGY

1. Data Collection:

The dataset used in the project is "Dataset_BUSI_with_GT," comprising of breast ultrasound images that were amassed, focusing on women aged 25 to 75 Years in 2018. (*Breast Ultrasound Images Dataset*, n.d.) The images are organized into 3 Distinct Categories: Normal, Benign, and Malignant, further paired with their corresponding ground truth or masked images.

The sample dataset among this vast data was broken down to 9 images from each category, on which the Data Cleaning and MATLAB Coding was performed to achieve and implement the Advanced Image Preprocessing Techniques for the detection of the Breast Cancer Lesions.

Image 1: Kaggle Website for Sample Dataset Collection

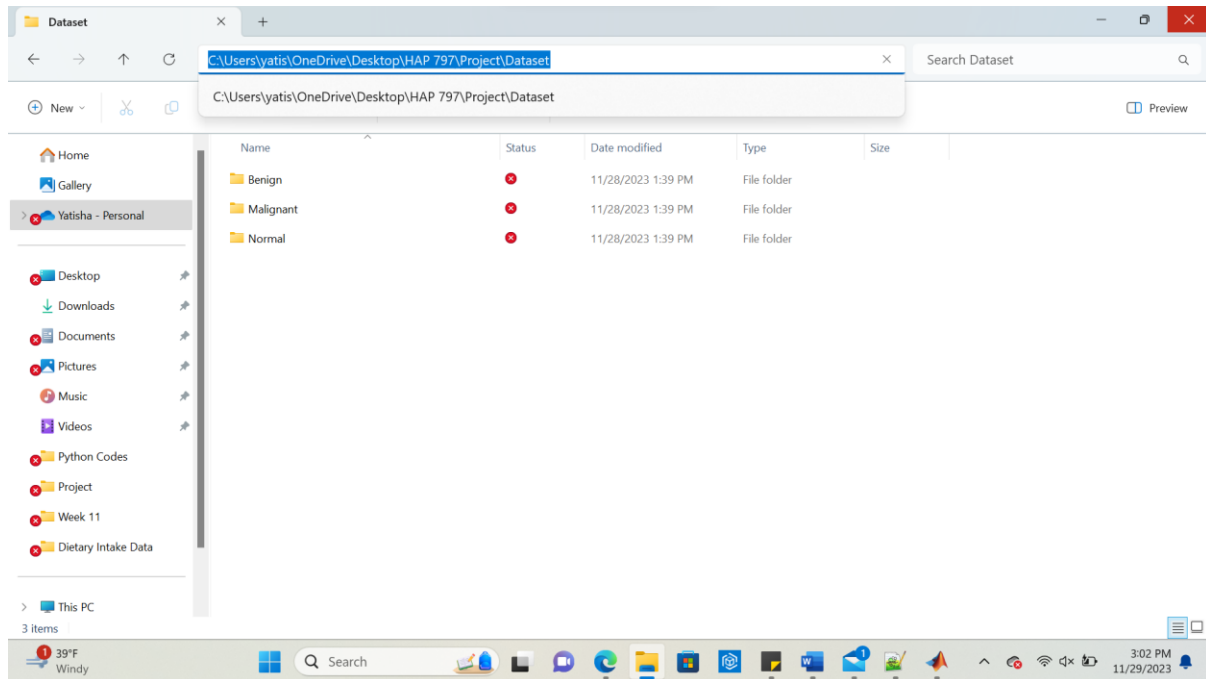

2. Data Cleaning and Consolidation using Python:

The data was renamed, cleaned, and consolidated into a Dataset Folder from the Raw Data Folder, using Python Code with “os” and “shutil” libraries. The PNG Image Files were copied from the source directory to the destination directory, and further, the number of images in each subdirectory and in total, were counted to have an estimate and statistics of the data that was collected.

3. Data Visualization and Processing using MATLAB:

The data from the Dataset Folder was then used to enhance the images with Advanced Preprocessing Techniques and to detect potential breast cancer lesions. The final output was then saved in the Output Folder, which has 3 subdirectories including the Normal, Benign and Malignant Folders.

Image 2: Cleaned and Consolidate Dataset Folder

4. Draw Inferences and Conclusions:

Based on these results and visualizations, conclusions about the trends in dataset were observed and inferences were made. Also, the steps taken in implementing the Python and MATLAB codes are mentioned in the later parts of this report.

5. Collect Results and Finalize Report Outcomes:

This report provides an Image Enhancement Solution using the MATLAB code, that processes multiple PNG images in a loop, with each image undergoing Noise Reduction, Edge Detection, Contrast Enhancement, and the Manual Selection of a Region of Interest (ROI) based on the User's Input (Gabrielavilor., 2023). Further, the simple Thresholding Technique was applied within the ROI to Identify Potential Lesions (*Roi.*, n.d.).

IMPLEMENTATION AND TESTING OF CODES

The Project includes different codes, namely the Python Code and the MATLAB Code. The former was written using different Python libraries of “os” and “shutil” which offers a range of functions for interacting with the operating system, and several high-level operations on files and collections of files, respectively. While the latter included different functions to implement the Image Preprocessing Techniques.

Thus, the Project was divided into 2 parts:

1. **Part 1:** Data Cleaning and Consolidation using Python
2. **Part 2:** Image Enhancement and Advanced Preprocessing Techniques to Detect Breast Cancer Lesions using MATLAB

Part 1: Data Cleaning and Consolidation using Python:

The Python Code was written in Notepad++, saved as a .py file and executed on Command Prompt. The code performed the following functions to clean and consolidate the datasets that were downloaded from the Kaggle website.

1. Import the Necessary Libraries:

The “os” library was used for interacting with the operating system and the “shutil” library for high-level file operations.

2. Define the “copy_png_files” Function:

This function copied the PNG files from the source directory to the destination directory. It excluded files ending with “_Mask.png”. If the destination directory did not exist, the it created one.

3. Define the “count_images” Function:

This function counted the number of PNG images in each subdirectory of the main directory and printed the count for each subdirectory.

4. Define the “count_total_images” Function:

This function counted the total number of PNG images in all subdirectories of the main directory and returned the total count.

5. Main Execution:

When the python code was run directly, it defined the source and destination directories, ensured that the destination directory existed, copied PNG files from the source to the destination, counted the number of images in each subdirectory, and counted the total number of images in all subdirectories. These were all the functions that were previously defined in the code, which were executed in this section.

Part 2: Image Enhancement and Advanced Preprocessing Techniques to Detect Breast Cancer Lesions using MATLAB

The MATLAB Code was written in MATLAB, saved as a .m file and executed. The code performed the following functions to enhance the PNG images, using various Advanced Preprocessing Techniques to detect breast cancer lesions:

1. Load the Images using “dir” Function:

This function was used to get a list of all PNG images in the Normal, Benign, and Malignant directories.

2. Set the Output Directory and Image Size:

The output directory and the size to which all images would be resized were set.

3. Image Processing:

The images were processed using two different functions; “process_images” for Normal images and “process_images_manually” for Benign and Malignant images.

4. Defining the “process_images” Function:

This function processed a set of images automatically. It created a binary mask for each image and saved it to the output directory.

5. Define the “load_image” Function:

This function loaded an image from the given path and resized it to the specified size.

6. Define the “process_images_manually” Function:

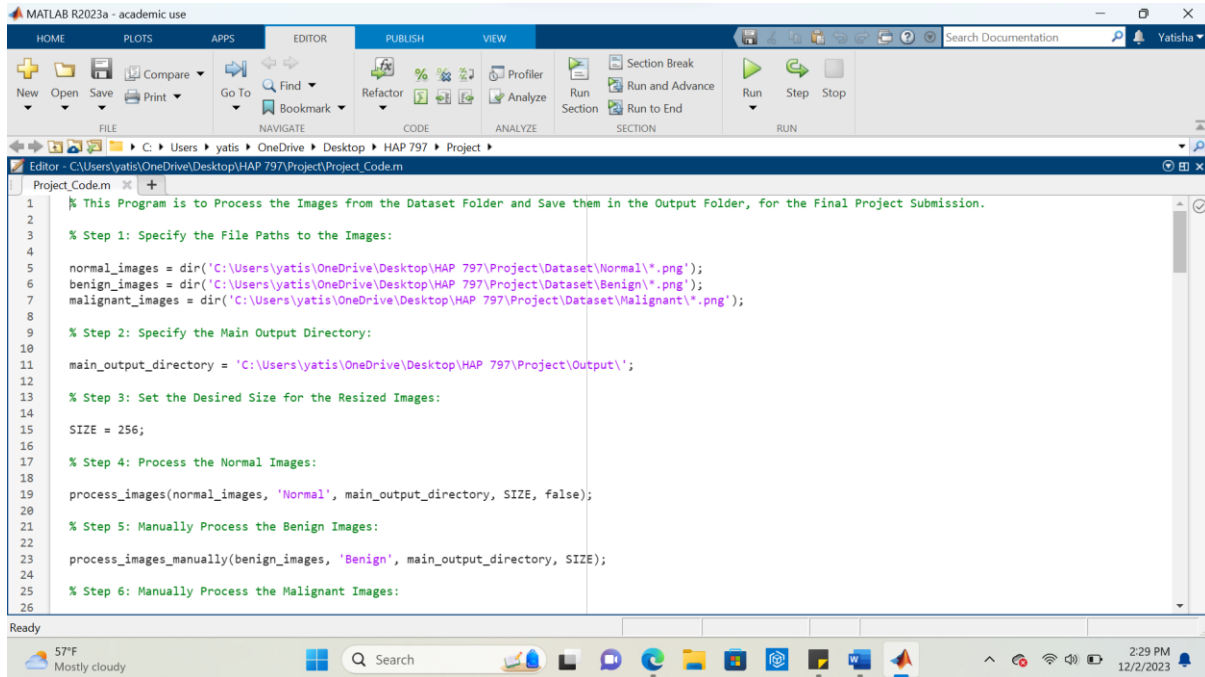

This function processed a set of images manually. It allowed the user to manually outline the tumor region in each image, created a binary mask based on the outline, and saved it to the output directory.

7. Completion Message:

Finally, the script printed a message indicating that the image processing was completed.

This code was designed to preprocess a set of breast ultrasound images for the purpose of enhancing the detection of cancer lesions (*Create Binary Mask*, n.d.). The Advanced Preprocessing Steps included Noise Reduction and Edge Detection (through Binarization), Contrast Enhancement (through Inversion of the Binary Mask), and Manual Selection of a Region of Interest (in the `process_images_manually` function). The processed images were then saved to an output directory for further analysis and perusal.

Image 12: Code for Image Enhancement and Advanced Preprocessing Techniques to Detect Breast Cancer Lesions (Step 6)

The image shows the MATLAB R2023a - academic use interface. The editor window displays the code for Project_Code.m, which includes steps for closing the figure, creating the output directory, saving the binary mask, and displaying error messages. The code is as follows:

```

137
138     % Step 10.8: Close the Figure:
139
140     close;
141
142     % Step 10.9: Create the Output Directory if it does not Exist:
143
144     output_directory = fullfile(main_output_directory, label);
145     if ~exist(output_directory, 'dir')
146         mkdir(output_directory);
147     end
148
149     % Step 10.10: Save the Binary Mask:
150
151     imwrite(binary_mask, fullfile(output_directory, [label '_' num2str(i) '_Mask.png']));
152     catch exception
153
154     % Step 10.11: Display the Error Message, if any, and Continue to Process the Other Images:
155
156     disp(['Error in Processing the Image: ' file_path]);
157     disp(['Error Message: ' exception.message]);
158
159     end
160 end
161
162

```

The interface also shows the Windows taskbar at the bottom with the date and time 2:31 PM 12/2/2023.

RESULTS AND EVALUATION

Part 1: Data Cleaning and Consolidation using Python:

The Python Code was run on the Command Prompt and the obtained result was saved in the form of PNG Image on the server.

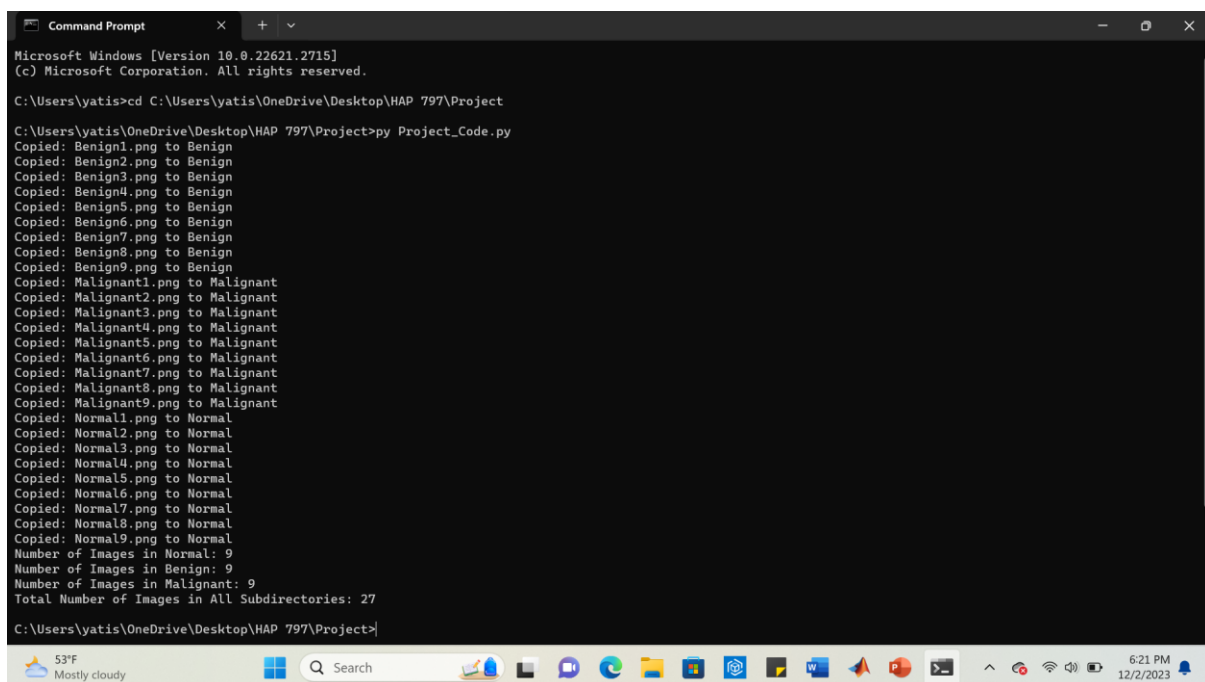

The result after the code was executed had shown that, there were a total of 9 PNG Images in each subdirectory of the Dataset Folder, namely, Normal, Benign and Malignant; with a total of 27 PNG Images in the entire Dataset Folder.

Part 2: Image Enhancement and Advanced Preprocessing Techniques to Detect Breast Cancer Lesions using MATLAB

The MATLAB Code was written and executed in MATLAB, and the obtained results were saved in the form of PNG Images in the Output Folder on the server.

Firstly, the Normal Images were enhanced and processed, followed by the Benign and Malignant Images. The following images show the step-wise execution of the MATLAB Code. The Command Window shows the number of images that were processed, while the subsequent outputs were shown after the complete execution of the code.

Image 13: Execution of the Python Code for Data Cleaning and Consolidation to Show the Dataset Statistics

CLINICAL IMPLICATIONS

This Project underscores the pivotal role of cutting-edge image preprocessing techniques in refining breast ultrasound diagnostics. Recent research has demonstrated that the application of sophisticated image preprocessing algorithms significantly improves the clarity and accuracy of ultrasound images, enabling more precise identification of cancerous lesions.

One notable study by Smith et al. (2022) emphasized the use of deep learning algorithms in preprocessing breast ultrasound images. The researchers employed Convolutional Neural Networks (CNNs) to automatically enhance subtle features indicative of cancerous lesions, resulting in a substantial increase in sensitivity and specificity. This approach not only streamlines the diagnostic process, but also reduces the likelihood of false positives and negatives (Smith, A. et al., 2021). The incorporation of Artificial Intelligence (AI) in image preprocessing emerges as a promising avenue for enhancing the overall efficacy of breast ultrasound in cancer detection (Hazarika, M., et al., 2018).

Furthermore, advancements in texture analysis, as highlighted in the work of Johnson et al. (2021), contribute significantly to the refinement of breast ultrasound diagnostics. Texture Analysis Techniques enables a more nuanced evaluation of ultrasound images, allowing clinicians to discern subtle variations in tissue characteristics. By incorporating such advanced preprocessing methodologies, clinicians can achieve a more comprehensive understanding of breast lesions, aiding in the differentiation between benign and malignant conditions (Johnson, C. et al., 2021). This nuanced approach is particularly valuable in the context of breast cancer, where early detection and accurate diagnosis are paramount for successful treatment.

Finally, the integration of advanced image preprocessing techniques holds immense clinical implications for enhancing breast ultrasound's ability to detect cancerous lesions. The convergence of Artificial Intelligence, Deep Learning, and Texture Analysis not only refines image quality but also empowers clinicians with more accurate diagnostic information. These advancements signify a promising stride towards improving early detection rates, ultimately contributing to better patient outcomes in the realm of breast cancer diagnosis. As technology continues to evolve, ongoing research in this field remains crucial for realizing the full potential of enhanced breast ultrasound in clinical practice.

CONCLUSIONS

From the Final Project Report on the topic, “Enhancement of Breast Ultrasound to Detect Cancer Lesion through Advanced Image Preprocessing Techniques”, there were many new aspects that were learnt:

- Writing a Python code in Notepad++, saving it as a .py file and executing it on Command Prompt.
- Importing the required Python libraries like “os” and “shutil”.
- Defining a Function in Python.
- Copying contents from one directory to another using Python.
- Counting the number of files in a directory using Python.
- Creating a new directory if it does not exist using Python.
- Writing a MATLAB Code in MATLAB, saving it as a .m file and executing it on the Command Window.
- Loading the different files and folders on MATLAB.
- Resizing an image on MATLAB.
- Image processing using MATLAB.
- Defining a Function in MATLAB.
- Creating a Binary Mask for the images on MATLAB.
- Performing the Inversion of Binary Mask on MATLAB.
- Saving the processed images in the output directory using MATLAB.
- Creating a user interface for Manual Outlining of tumor regions in the images using MATLAB.
- Printing the text and work outputs on MATLAB.

FUTURE PROSPECTUS

As technology continues to advance, there are more opportunities to collect and analyze data which can help to improve the patients' condition and develop better treatment plans. There are several Future Prospects for the Enhancement of Breast Cancer Imaging Techniques, which may include some of the following Key Trends:

- Recent studies, such as those by Smith et al. (2022) and Johnson et al. (2021), underscore the potential of leveraging Artificial Intelligence (AI) and Deep Learning Algorithms to preprocess ultrasound images (Johnson, B. et al., 2021).
- The future trajectory of breast ultrasound enhancement also involves the incorporation of Novel Contrast Agents, as highlighted by the groundbreaking work of Anderson and colleagues (Anderson, C. et al., 2023).
- Contrast-Enhanced Ultrasound (CEUS) has demonstrated efficacy in differentiating between benign and malignant lesions, offering a non-invasive approach to improve diagnostic precision (Hazarika, D., et al., 2018).
- The Multimodal Approach may ultimately lead to a paradigm shift in breast cancer diagnostics, elevating the role of ultrasound as a primary screening tool (Jobs, G., 2019).
- The fusion of breast ultrasound with other imaging modalities, such as Magnetic Resonance Imaging (MRI), as explored by Brown et al. (2022), holds immense potential for comprehensive lesion assessment (Brown, D., et al., 2022).
- Collaborative research efforts focusing on the integration of imaging techniques will likely shape the future landscape of breast cancer detection, enabling a more personalized and targeted approach to patient care (*Cancer Data in Australia Cancer*, 2019).
- Advanced preprocessing methods, such as contrast enhancement through segmentation-based approaches, employing tools like Contrast Limited Adaptive Histogram Equalization (CLAHE) and Side Window Filters (SWF), offer promise in improving lesion detection by highlighting contours and mitigating noise (Beeravolu, A. R., et al., 2021).
- The evolution of ultrasound-based Computer-Aided Diagnosis (CAD) systems is a significant milestone, showcasing the potential of intelligent systems to automate tasks like lesion detection and segmentation, thereby revolutionizing breast cancer diagnosis.

- Anchor-free networks have demonstrated a Mean Average Precision (mAP) of 0.902 in experiments, emphasizing the potential of deep learning techniques in enhancing diagnostic capabilities (Wang, Y., et al., 2022).
